

Yes. Since **you plan to host the website yourself**, the best approach is **not to scrape the live preview website**. If this is a site you created in Emergent, get the **actual project source from Emergent/GitHub**. Emergent explicitly supports code ownership, GitHub sync, and exporting/hosting the code elsewhere.  Emergent +1

Recommended method: Export via GitHub

If you still have access to the Emergent project that produced:

gabatia-projects.preview.emergentagent.com

do this:

1. Open the project in **Emergent**.
2. Connect your **GitHub account**.
3. Use **Save to GitHub**.
4. Select/create a repository, e.g. `gabatia-website`.
5. Let Emergent push the complete project.
6. Clone/download the GitHub repository.
7. You now have the actual source code, including the frontend and any backend/configuration files.

Emergent's documentation specifically says its GitHub integration can push the project to your repository and later import/pull it back.  Emergent

If you don't want GitHub

Emergent also supports **exporting the project/code**, and its current documentation states that you own the generated code and can host it independently.  Emergent +1

Look in the project interface for an option such as **Export / Download Code**. A ZIP should give you something resembling:

```
gabatia-website/
├─ frontend/
│   └─ src/
│   └─ public/
│   └─ package.json
│   └─ ...
├─ backend/           # if the project has one
├─ .env.example
├─ README.md
└─ ...
```

The exact structure depends on what Emergent generated.

Important distinction

The URL you gave me is a **Preview URL**, not the source repository. Emergent describes preview URLs as temporary development environments; the preview can stop after inactivity.  Emergent

So don't try to reconstruct the project by downloading the page from Chrome. That would generally give you the built HTML/JS/CSS assets, not the original React source, components, project configuration, or backend.

If you no longer have access to the Emergent project

That's a different situation.

I can inspect the **public-facing site** and help reconstruct the frontend, but we wouldn't be able to recover the original source code, component structure, or backend simply from the preview URL.

Since your goal is to **use the existing Gabatia site as the starting point and then host it yourself**, I'd strongly recommend:

Emergent project → GitHub → your hosting

rather than:

Live preview → scrape website → rebuild

Emergent's current documentation explicitly supports the first workflow and says you can deploy the exported code anywhere you want.  Emergent

If you tell me **where you're planning to host it (Vercel, Netlify, Hostinger, cPanel, or your own VPS)**, I can give you the exact export → build → deployment steps.
